

Lecture Notes – The Julia Set

Josh Lipschultz & Ricky LeVan

Preliminaries

As a quick recap of what we saw last week, recall the following facts. First, for the quadratic map $Q_0(z) = z^2$ we saw chaotic behavior only on S^1 by angle doubling ($\theta \rightarrow 2\theta$). We also saw that $|Q_0(z)| \rightarrow \infty$ for all $|z| > 1$ and $|Q_0(z)| \rightarrow 0$ for all $|z| < 1$.

We also defined the Julia Set J_c as the boundary of the filled Julia set K_c . (The filled Julia set is the set of bounded points of Q_c .) We could alternatively define J_c as the closure of the set of repelling points of Q_c (in fact, this definition isn't limited to the quadratic map; any polynomial will do, and is denoted $J(P)$ for some $P : \mathbb{C} \rightarrow \mathbb{C}$).

The *stable set* of a complex polynomial P , denoted $S(P)$, is the complement of $J(P)$.

Another useful definition was that of a *bounded orbit*. An orbit is bounded if there exists a K such that $|Q_c^{(n)}(z)| < K$ for all n . Otherwise the orbit is *unbounded*.

The previous group also discussed how the points of S^1 were *supersensitive*. That is, any open ball around $z \in S^1$ has the property that $\bigcup_{n=0}^{\infty} Q_0^{(n)}(z) = \mathbb{C} \setminus \{p\}$ for at most one point p .

Finally, as a reminder, the *filled Julia set* is the set of bounded points of Q_c , and the Julia set

16.3 – The Julia Set as a Cantor Set

For this section of the talk, we will consider the family of quadratic functions $Q_c(z) = z^2 + c$ when $|c| > 2$.

The first big Theorem we will discuss, not in complete detail, is the following.

Theorem 1. Suppose $|c| > 2$. Then $J_c = K_c$ is a Cantor set. Moreover, the quadratic map Q_c , when restricted to J_c , is conjugate to the shift map on two symbols.

Theorem 2 (The Escape Criterion).

Corollary 1.

Corollary 2.

Corollary 3.
